#### State of the Art

Hepatitis C virus (HCV) causes a liver damaging infection that can lead to cirrhosis, liver failure or liver cancer, and eventually death. HCV is an enveloped virus containing a positive-sense single-stranded RNA genome of approximately 9.4 kb, and has a virion size of 30-60 nm.<sup>1</sup>

HCV is a major causative agent for post-transfusion and for sporadic non-A, non-B hepatitis. Infection by HCV is insidious in a high proportion of chronically infected (and infectious) carriers who may not experience clinical symptoms for many years.

HCV is difficult to treat and it is estimated that there are 500 million people infected with it worldwide. No effective immunization is currently available, and hepatitis C can only be controlled by other preventive measures such as improvement in hygiene and sanitary conditions and interrupting the route of transmission.

At present, the only acceptable treatment for chronic hepatitis C is interferon (IFN-alpha) and this requires at least six (6) months of treatment and/or ribavirin, which can inhibit viral replication in infected cells and also improve liver function in some people.

IFN-alpha belongs to a family of naturally occurring small proteins with characteristic biological effects such as antiviral, immunoregulatory and antitumoral activities which are produced and secreted by most animal nucleated cells in response to several diseases, in particular viral infections. IFN-alpha is an important regulator of growth and differentiation affecting cellular communication and immunological control. Treatment of HCV with interferon, however, has limited long term efficacy with a response rate about 25%. In addition, treatment of HCV with interferon has frequently been associated with adverse side effects such as fatigue, fever, chills, headache, myalgias, arthralgias, mild alopecia, psychiatric effects and associated disorders, autoimmune phenomena and associated disorders and thyroid dysfunction.

Ribavirin (1- $\beta$ -D-ribofuranosyl-1 H-1,2,4-triazole-3-carboxamide), an inhibitor of inosine 5'-monophosphate dehydrogenase (IMPDH), enhances the efficacy of IFN-alpha in the treatment of HCV. Despite the introduction of ribavirin, more than 50% of the patients do not eliminate the virus with the current standard therapy of interferon-alpha (IFN) and ribavirin. By now, standard therapy of chronic hepatitis C has been changed to the combination of PEG-IFN plus ribavirin. However, a number of patients still have significant side effects, primarily related to ribavirin. Ribavirin causes significant hemolysis in 10-20% of patients treated at currently recommended doses, and the drug is both teratogenic and embryotoxic.

Other approaches are being taken to combat the virus. They include, for example, application of antisense oligonucleotides or ribozymes for inhibiting HCV replication. Furthermore, low-molecular weight compounds that directly inhibit HCV proteins and interfere with viral replication are considered as attractive strategies to control HCV infection. NS3/4A serine protease, ribonucleic acid (RNA) helicase, RNA-dependent RNA polymerase are considered as potential targets for new drugs.<sup>2,3</sup>

Devos, *et al.*<sup>4</sup> describes purine and pyrimidine nucleoside derivatives and their use as inhibitors of HCV RNA replication. Sommadossi, *et al.*<sup>5</sup> describes 1', 2' or 3'-modified nucleosides and their use for treating a host infected with HCV. Carroll, *et al.*<sup>44, 45</sup>, both of which published after the filing of the present application, describe nucleosides as inhibitors of RNA-dependent RNA viral polymerase. Applicants do not intend to cover any compounds specifically disclosed in these applications.

Given the fact of the worldwide epidemic level of HCV, there is a strong need for new effective drugs for HCV treatment. The present invention provides nucleoside derivatives for treating HCV infections.

A. General Synthesis of 2'-C-Branched Nucleosides

5

2'-C-Branched ribonucleosides of the following structures:

1a

1b

10 where R<sup>1</sup>, R<sup>2</sup>, W, X, Y and Z are as defined above, can be prepared by one of the following general methods.

1. *Convergent approach: Glycosylation of Nucleobase with Appropriately Modified Sugar*

15

The key starting material of this process is an appropriately substituted sugar with 2'-OH and 2'-H with the appropriate leaving group, for example an acyl group or a chloro, bromo, fluoro or iodo. The sugar can be purchased or can be prepared by any known means including standard epimerization, substitution, oxidation and reduction techniques. For example, commercially available 1,3,5- tri-O-benzoyl- $\alpha$ -D-ribofuranose (Pfanstiel Laboratories, Inc.) can be used. The substituted sugar can then be oxidized with the appropriate oxidizing agent in a compatible solvent at a suitable temperature to yield the 2'-modified sugar. Possible oxidizing agents are, for example, Dess-Martin periodine reagent, Ac<sub>2</sub>O+ DCC in DMSO, Swern oxidation (DMSO, oxalyl chloride, triethylamine), Jones reagent (a mixture of chromic acid and

25

sulfuric acid), Collins's reagent (dipyridine Cr(VI) oxide, Corey's reagent (pyridinium chlorochromate), pyridinium dichromate, acid dichromate, potassium permanganate, MnO<sub>2</sub>, ruthenium tetroxide, phase transfer catalysts such as chromic acid or permanganate supported on a polymer, Cl<sub>2</sub>-pyridine, H<sub>2</sub>O<sub>2</sub>-ammonium molybdate, NaBrO<sub>2</sub>-CAN, NaOCl in HOAc, copper chromite, copper oxide, Raney nickel, palladium acetate, Meerwin-Pondorf-Verley reagent (aluminum *t*-butoxide with another ketone) and *N*-bromosuccinimide.

Coupling of an organometallic carbon nucleophile, such as a Grignard reagent, an organolithium, lithium dialkylcopper or R<sup>1</sup>-SiMe<sub>3</sub> in TBAF with the ketone with the appropriate non-protic solvent at a suitable temperature, yields the 2'-alkylated sugar. For example, R<sup>1</sup>MgBr/TiCl<sub>4</sub> or R<sup>1</sup>MgBr/CeCl<sub>3</sub> can be used as described in Wolfe et al. 1997. *J. Org. Chem.* 62: 1754-1759. The alkylated sugar can be optionally protected with a suitable protecting group, preferably with an acyl, substituted alkyl or silyl group, by methods well known to those skilled in the art, as taught by Greene et al. *Protective Groups in Organic Synthesis*, John Wiley and Sons, Second Edition, 1991.

The optionally protected sugar can then be coupled to the purine or pyrimidine base by methods well known to those skilled in the art, as taught by Townsend *Chemistry of Nucleosides and Nucleotides*, Plenum Press, 1994. For example, an acylated sugar can be coupled to a silylated base with a Lewis acid, such as tin tetrachloride, titanium tetrachloride or trimethylsilyltriflate in the appropriate solvent at a suitable temperature. Alternatively, a halo-sugar can be coupled to a silylated base with the presence of trimethylsilyltriflate.

Scheme 1 below describes the alternative synthesis of a protected sugar that is useful for coupling to bases where the connection to the base is on a carbon atom instead of a nitrogen atom.

Scheme 1: Alternative Sugar Synthesis and Coupling

- 5            Formation of sugar **a** in Scheme 1, above, is accomplished as described by Mandal, S.B., *et al.*, *Synth. Commun.*, 1993, **9**, page 1239, starting from commercial D-ribose. Protection of the hydroxyl groups to form sugar **b** is described in Witty, D.R., *et al.*, *Tet. Lett.*, 1990, **31**, page 4787. Sugar **c** and **d** are prepared using the method of Ning, J. *et al.*, *Carbohydr. Res.*, 2001, **330**, page 165, and methods
- 10           described herein. R, in Sugar **e** can be hydrogen, alkyl, substituted alkyl, alkenyl, substituted alkenyl, alkynyl, and substituted alkynyl. Particularly preferred R groups are methyl, trifluoromethyl, alkenyl and alkynyl. Sugar **e** is prepared by using a modification of the Grignard reaction withn RMgBr or other appropriate organometallic as described herein (with no Titanium/cerium needed). Finally the
- 15           halogenated sugar used in the subsequent coupling reaction is prepared using the same protection method as used in to make sugar **b** above. The halogenation is described in Seela.<sup>17</sup>

20           Subsequently, any of the described nucleosides can be deprotected by methods well known to those skilled in the art, as taught by Greene *et al.* *Protective Groups in Organic Synthesis*, Jon Wiley and Sons, Second Edition, 1991.

In a particular embodiment, the 2'-C-branched ribonucleoside is desired.

25           2.            *Linear Approach: Modification of a pre-formed nucleoside*

The key starting material for this process is an appropriately substituted nucleoside with a 2'-OH and 2'-H. The nucleoside can be purchased or can be prepared by any known means including standard coupling techniques. The nucleoside can be optionally protected with suitable protecting groups, preferably with acyl, substituted alkyl or silyl groups, by methods well known to those skilled in the art, as taught by Greene *et al.* *Protective Groups in Organic Synthesis*, John Wiley and Sons, Second Edition, 1991.

The appropriately protected nucleoside can then be oxidized with the appropriate oxidizing agent in a compatible solvent at a suitable temperature to yield the 2'-modified sugar. Possible oxidizing agents are, for example, Dess-Martin periodine reagent,  $\text{Ac}_2\text{O} + \text{DCC}$  in DMSO, Swern oxidation (DMSO, oxalyl chloride, triethylamine), Jones reagent (a mixture of chromic acid and sulfuric acid), Collins's reagent (dipyridine Cr(VI) oxide, Corey's reagent (pyridinium chlorochromate), pyridinium dichromate, acid dichromate, potassium permanganate,  $\text{MnO}_2$  ruthenium tetroxide, phase transfer catalysts such as chromic acid or permanganate supported on a polymer,  $\text{Cl}_2$ -pyridine,  $\text{H}_2\text{O}_2$ -ammonium molybdate,  $\text{NaBrO}_2$ -CAN,  $\text{NaOC1}$  in HOAc, copper chromite, copper oxide, Raney nickel, palladium acetate, Meerwin-Pondorf-Verley reagent (aluminum *t*-butoxide with another ketone) and *N*-bromosuccinimide. Coupling of an organometallic carbon nucleophile, such as a Grignard reagent, an organolithium, lithium dialkylcopper or  $\text{R}^1\text{-SiMe}_3$  in TBAF with the ketone with the appropriate non-protic solvent at a suitable temperature, yields the appropriate substituted nucleoside.

Subsequently, the nucleoside can be deprotected by methods well known to those skilled in the art, as taught by Greene *et al.* *Protective Groups in Organic Synthesis*, John Wiley and Sons, Second Edition, 1991.

In a particular embodiment, the 2'-C-branched ribonucleoside is desired. In another embodiment of the invention, the L-enantiomers are desired. Therefore, the L-enantiomers can be corresponding to the compounds of the invention can be

prepared following the same foregoing general methods, beginning with the corresponding L-sugar or nucleoside L-enantiomer as starting material.

Possible oxidizing agents are, for example, Dess-Martin periodine reagent, Jones reagent (a mixture of chromic acid and sulfuric acid),  
25 Collins's reagent (dipyridine Cr(VI) oxide, Corey's reagent (pyridinium

chlorochromate), pyridinium dichromate, acid dichromate, potassium permanganate, MnO<sub>2</sub>, ruthenium tetroxide, phase transfer catalysts such as chromic acid or permanganate supported on a polymer, Cl<sub>2</sub>-pyridine, H<sub>2</sub>O<sub>2</sub>-ammonium molybdate, NaBrO<sub>2</sub>-CAN, NaOCl in HOAc, copper chromite, copper oxide, Raney nickel, 5 palladium acetate, Meerwin-Pondorf-Verley reagent (aluminum *t*-butoxide with another ketone) and *N*-bromosuccinimide.

Then coupling of an organometallic carbon nucleophile, such as a Grignard reagent, an organolithium, lithium dialkylcopper or R-SiMe<sub>3</sub> in TBAF with the 10 ketone with the appropriate non-protic solvent at a suitable temperature, yields the 3'-C-branched sugar. For example, RMgBr/TiCl<sub>4</sub> or RMgBr/CeCl<sub>3</sub> can be used as described in Wolfe et al. 1997. *J. Org. Chem.* 62: 1754-1759. The 3'-C-branched sugar can be optionally protected with a suitable protecting group, preferably with an acyl or silyl group, by methods well known to those skilled in the art, as taught by 15 Greene et al. *Protective Groups in Organic Synthesis*, John Wiley and Sons, Second Edition, 1991.

The optionally protected sugar can then be coupled to the base by methods well known to those skilled in the art, as taught by Townsend *Chemistry of* 20 *Nucleosides and Nucleotides*, Plenum Press, 1994. For example, an acylated sugar can be coupled to a silylated base with a Lewis acid, such as tin tetrachloride, titanium tetrachloride or trimethylsilyltriflate in the appropriate solvent at a suitable temperature. Alternatively, a halo-sugar can be coupled to a silylated base with the presence of trimethylsilyltriflate.

25 Subsequently, the nucleoside can be deprotected by methods well known to those skilled in the art, as taught by Greene et al. *Protective Groups in Organic Synthesis*, John Wiley and Sons, Second Edition, 1991.

30 In a particular embodiment, the 3'-C-branched ribonucleoside is desired. Alternatively, deoxyribonucleoside is desired. To obtain these nucleosides, the formed ribonucleoside can optionally be protected by methods well known to those

skilled in the art, as taught by Greene *et al.* *Protective Groups in Organic Synthesis*, John Wiley and Sons, Second Edition, 1991, and then the 2'-OH can be reduced with a suitable reducing agent. Optionally, the 2'-hydroxyl can be activated to facilitate reduction; i.e. via the Barton reduction.

## 2. Linear Approach: Modification of a pre-formed nucleoside

The key starting material for this process is an appropriately substituted nucleoside with a 3'-OH and 3'-H. The nucleoside can be purchased or can be prepared by any known means including standard coupling techniques. The nucleoside can be optionally protected with suitable protecting groups, preferably with acyl or silyl groups, by methods well known to those skilled in the art, as taught by Greene *et al.* *Protective Groups in Organic Synthesis*, John Wiley and Sons, Second Edition, 1991.

The appropriately protected nucleoside can then be oxidized with the appropriate oxidizing agent in a compatible solvent at a suitable temperature to yield the 3'-modified sugar. Possible oxidizing agents are, for example, Dess-Martin periodine reagent, Jones reagent (a mixture of chromic acid and sulfuric acid), Collins's reagent (dipyridine Cr(VI) oxide), Corey's reagent (pyridinium chlorochromate), pyridinium dichromate, acid dichromate, potassium permanganate, MnO<sub>2</sub>, ruthenium tetroxide, phase transfer catalysts such as chromic acid or permanganate supported on a polymer, Cl<sub>2</sub>-pyridine, H<sub>2</sub>O<sub>2</sub>-ammonium molybdate, NaBrO<sub>2</sub>-CAN, NaOCl in HOAc, copper chromite, copper oxide, Raney nickel, palladium acetate, Meerwin-Pondorf-Verley reagent (aluminum *t*-butoxide with another ketone) and *N*-bromosuccinimide.

30

Subsequently, the nucleoside can be deprotected by methods well known to those skilled in the art, as taught by Greene *et al.* *Protective Groups in Organic Synthesis*, John Wiley and Sons, Second Edition, 1991.

In a particular embodiment, the 3'-C-branched ribonucleoside is desired. Alternatively, deoxyribonucleoside is desired. To obtain these nucleosides, the

formed ribonucleoside can optionally be protected by methods well known to those skilled in the art, as taught by Greene *et al. Optionally, the 2'-hydroxyl can be activated to facilitate  
5 reduction; i.e. via the Barton reduction.

In another embodiment of the invention, the L-enantiomers are desired. Therefore, the L-enantiomers can be corresponding to the compounds of the invention can be prepared following the same foregoing general methods, beginning  
10 with the corresponding L-sugar or nucleoside L-enantiomer as starting material.

#### C. General Synthesis of Purine Bases of Formula Ia and Pyrimidines Bases of Formula Ib

The purine bases of formula I-IVa and pyrimidines bases of formula I-IVb for  
15 above condensation reactions can be obtained commercially or can be prepared by procedures known to the art.

The preparation of purine bases of formula I-IVa is reviewed by G. Shaw in "*Comprehensive Heterocyclic Chemistry*," Pergamon Press, Vol. 5, chapter 4.09, p.  
20 449 and "*Comprehensive Heterocyclic Chemistry II*" Pergamon Press, Vol. 7, chapter 7.11, p. 397.

The preparation of pyrimidines bases of formula I-IVb is reviewed by Brown D. "*The Chemistry of Heterocyclic Compounds – The Pyrimidines* " 1962 and  
25 Supplement 1, 1970 John Wiley and Sons, New York, by Brown D. in "*Comprehensive Heterocyclic Chemistry*," Pergamon Press Vol. 7, chapter 4.09, p. 499 and by K. Unheim and T. Benneche in "*Comprehensive Heterocyclic Chemistry II*" Pergamon Press Vol. 6 chapter 6.02, p. 93.

30 For example, the appropriate purine base of formula I-IVa may be prepared from the corresponding purine wherein the 2, 6 or 8 position of the purine base is substituted with a suitable leaving group such as halogen or sulphonate. Such purine

precursors bearing leaving groups are available commercially, e.g. 6-chloropurine (Aldrich Chemical Company), 2,6-dichloropurine (Aldrich Chemical Company), 2-chloro-6-aminopurine (Aldrich Chemical Company), 8-bromoadenine (Sigma-Aldrich Company Limited) or obtained by procedures known in the art. For example

5 2- and 6-chloro substituted purines can be prepared by chlorination of the corresponding 2 and 6-hydroxypurines respectively by the use of chlorinating agents such as phosphorus oxychloride (Bakuni et al. *Indian J. Chem.*, Sect B 1984, 23, 1286; LaMontagne et al. *J. Heterocycl. Chem.* 1983, 20, 295) while introduction of a

10 bromine into the 8-position of purines can be accomplished by direct bromination using brominating agents such as, for example, bromine (Mano et al, *Chem Pharm Bull* 1983, 31, 3454) or N-bromosuccinimide (Kelley et al. *Heterocycl. Chem.* 1990, 27, 1505). The purines where the 6-substituent is alkoxy, aryloxy, SH, alkylthio, arylthio, alkylamino, cycloalkylamino, saturated cyclic amino, nitrogen linked heteroaromatic, hydroxylamino, alkoxylamino, hydrazine, alkylhydrazino may be

15 prepared by treatment of the corresponding 6-halopurine with the appropriate alkoxides, thiols, amines, nitrogen containing heterocycles, hydroxylamines and hydrazines, (for example, Chae et al. *J Med Chem*, 1994, 37, 342; Niebch and Schneider, *Z. Naturforsch. B.Anorg. Chem. Org. Chem. Biochem. Biophys. Biol.* 1972, 27, 675; LaMontagne et al., *Heterocycl Chem* 1983, 20, 295; Estep et al *J Med*

20 *Chem* 1995, 38, 2582). Similarly, 2-substituted purines can be prepared from the corresponding 2-halopurine, for example, purines where the 2-substituent is alkoxy, aryloxy, SH, alkylthio, arylthio or  $\text{NR}^3\text{R}^4$  can be prepared from the corresponding 2-halopurine by treatment with alkoxides, thiols or amines (e.g. Barlin and Fenn, *Aust J Chem*, 1983, 36, 633; Nugiel et al., *J Org Chem*, 1997, 62, 201). Similarly, 8-

25 substituted purines can be prepared from the corresponding 8-halopurines. For example purines where the 8-substituent is alkoxy, aryloxy, SH, alkylthio, arylthio or  $\text{NR}^3\text{R}^4$  can be prepared by treatment of the corresponding 8-bromopurine with the appropriate alkoxides, thiols or amines (Xing et al, *Tetrahedron Lett*, 1990, 31, 5849; Mano et al, *Chem Pharm Bull* 1983, 31, 3454). Where the 2, 6 or 8 substituent is a

30 cyclic amine moiety the purine can be prepared from the 6-aminopurine by reaction with an appropriate dialkylating agent such as dihaloalkane. In some cases where the 6-substituent is a nitrogen containing heteroaromatic linked through the nitrogen

atom the purine may be prepared from the 6-aminopurine by reaction with a dicarbonyl compound or a reactive derivative of this such as an acetal. For example 6-(1H-pyrrol-1-yl)-1H-purine can be prepared from a 6-chloropurine by reaction with 2,5-dimethoxytetrahydrofuran as described by Estep et al *J Med Chem* 1995, 38, 2582.

D. General Synthesis of 6-aryl(heteroaryl)/alkyl-substituted purine and 4- aryl(heteroaryl)/alkyl-substituted pyrimidine

Synthesis of 6-aryl(heteroaryl)/alkyl-substituted purines and 4- aryl(heteroaryl)/alkyl-substituted pyrimidines is shown in Scheme 2.

Scheme 2.

Commercial 341 is converted to the 2'-methyl-ribose derivative 342 as described in Wolfe, et al., *J. Org. Chem.*, 1997, 62, 1754. 6-Bromopurine 2'-

methylriboside (343) is prepared using the procedure for the synthesis of 6-chloropurine described in Wolfe, *et al.*, *J. Org. Chem.*, 1997, 62, 1754. 6-aromatic-substituted purine 2'-methylribosides 344 are synthesized using the protocols reported by Hocke *et al.*, *J. Med. Chem.*, 2000, 43, 1817 with commercially available boronic acids (R-M in Scheme 2). 6-alkyl-substituted purine 2'-methylribosides 344 are synthesized using modifications of the protocol reported by Bergstrom and Reday, *Tet. Lett.*, 1982, 23, 4191. 6-aromatic-substituted-2-amino-purine 2'-methylribosides 345 are synthesized using modification of the protocols reported by Lakshman *et al.*, *Org. Lett.*, 2002, 4, 1479 with commercially available boronic acids (R-B(OH)<sub>2</sub> in Scheme 2). 6-alkyl-substituted-2-amino-purine 2'-methylribosides 345 are synthesized using modifications of the protocol reported by Bergstrom and Reday, *Tet. Lett.*, 1982, 23, 4191.

In similar manner, but using the appropriate pyrimidine bases, 4-aryl(heteroaryl)/alkyl-substituted pyrimidines 348 are synthesized.

According to this protocol, the following nucleosides are prepared.

### Utility, Testing, and Administration

#### Utility

The present invention provides novel compounds possessing antiviral activity, including hepatitis C virus. The compounds of this invention inhibit HCV replication by inhibiting the enzymes involved in replication, including RNA dependent RNA polymerase. They may also inhibit other enzymes utilized in the activity or proliferation of HCV.

The compounds of the present invention can also be used as prodrug nucleosides. As such they are taken up into the cells and can be intracellularly phosphorylated by kinases to the triphosphate and are then inhibitors of the polymerase (NS5b) and/or act as chain-terminators.

Compounds of this invention may be used alone or in combination with other compounds to treat viruses.

#### Administration and Pharmaceutical Composition

In general, the compounds of this invention will be administered in a therapeutically effective amount by any of the accepted modes of administration for agents that serve similar utilities. The actual amount of the compound of this invention, i.e., the active ingredient, will depend upon numerous factors such as the severity of the disease to be treated, the age and relative health of the subject, the potency of the compound used, the route and form of administration, and other

factors. The drug can be administered more than once a day, preferably once or twice a day.

Therapeutically effective amounts of compounds of Formula Ia, Ib, Ic, II, IIA, III, or IV may range from approximately 0.05 to 50 mg per kilogram body weight of the recipient per day; preferably about 0.01-25 mg/kg/day, more preferably from about 0.5 to 10 mg/kg/day. Thus, for administration to a 70 kg person, the dosage range would most preferably be about 35-70 mg per day.

In general, compounds of this invention will be administered as pharmaceutical compositions by any one of the following routes: oral, systemic (e.g., transdermal, intranasal or by suppository), or parenteral (e.g., intramuscular, intravenous or subcutaneous) administration. The preferred manner of administration is oral using a convenient daily dosage regimen that can be adjusted according to the degree of affliction. Compositions can take the form of tablets, pills, capsules, semisolids, powders, sustained release formulations, solutions, suspensions, elixirs, aerosols, or any other appropriate compositions. Another preferred manner for administering compounds of this invention is inhalation. This is an effective method for delivering a therapeutic agent directly to the respiratory tract, in particular for the treatment of diseases such as asthma and similar or related respiratory tract disorders (see U. S. Patent 5,607,915).

The choice of formulation depends on various factors such as the mode of drug administration and bioavailability of the drug substance. For delivery via inhalation the compound can be formulated as liquid solution, suspensions, aerosol, propellants or dry powder and loaded into a suitable dispenser for administration. There are several types of pharmaceutical inhalation devices-nebulizer inhalers, metered dose inhalers (MDI) and dry powder inhalers (DPI). Nebulizer devices produce a stream of high velocity air that causes the therapeutic agents (which are formulated in a liquid form) to spray as a mist that is carried into the patient's respiratory tract. MDI's typically are formulation packaged with a compressed gas. Upon actuation, the device discharges a measured amount of therapeutic agent by

compressed gas, thus affording a reliable method of administering a set amount of agent. DPI dispenses therapeutic agents in the form of a free flowing powder that can be dispersed in the patient's inspiratory air-stream during breathing by the device. In order to achieve a free flowing powder, the therapeutic agent is formulated with an excipient such as lactose. A measured amount of the therapeutic agent is stored in a capsule form and is dispensed with each actuation.

Recently, pharmaceutical formulations have been developed especially for drugs that show poor bioavailability based upon the principle that bioavailability can be increased by increasing the surface area i.e., decreasing particle size. For example, U.S. Pat. No. 4,107,288 describes a pharmaceutical formulation having particles in the size range from 10 to 1,000 nm in which the active material is supported on a crosslinked matrix of macromolecules. U.S. Pat. No. 5,145,684 describes the production of a pharmaceutical formulation in which the drug substance is pulverized to nanoparticles (average particle size of 400 nm) in the presence of a surface modifier and then dispersed in a liquid medium to give a pharmaceutical formulation that exhibits remarkably high bioavailability.

The compositions are comprised of in general, a compound of Formula Ia, Ib, Ic, II, IIA, III, or IV in combination with at least one pharmaceutically acceptable excipient. Acceptable excipients are non-toxic, aid administration, and do not adversely affect the therapeutic benefit of the compound of Formula Ia, Ib, Ic, II, IIA, III, or IV. Such excipient may be any solid, liquid, semi-solid or, in the case of an aerosol composition, gaseous excipient that is generally available to one of skill in the art.

Solid pharmaceutical excipients include starch, cellulose, talc, glucose, lactose, sucrose, gelatin, malt, rice, flour, chalk, silica gel, magnesium stearate, sodium stearate, glycerol monostearate, sodium chloride, dried skim milk and the like. Liquid and semisolid excipients may be selected from glycerol, propylene glycol, water, ethanol and various oils, including those of petroleum, animal, vegetable or synthetic origin, e.g., peanut oil, soybean oil, mineral oil, sesame oil, etc.

Preferred liquid carriers, particularly for injectable solutions, include water, saline, aqueous dextrose, and glycols.

Compressed gases may be used to disperse a compound of this invention in aerosol form. Inert gases suitable for this purpose are nitrogen, carbon dioxide, etc. Other suitable pharmaceutical excipients and their formulations are described in Remington's Pharmaceutical Sciences, edited by E. W. Martin (Mack Publishing Company, 18th ed., 1990).

The amount of the compound in a formulation can vary within the full range employed by those skilled in the art. Typically, the formulation will contain, on a weight percent (wt%) basis, from about 0.01-99.99 wt% of a compound of Formula Ia, Ib, Ic, II, IIA, III, or IV based on the total formulation, with the balance being one or more suitable pharmaceutical excipients. Preferably, the compound is present at a level of about 1-80 wt%. Representative pharmaceutical formulations containing a compound of Formula Ia, Ib, Ic, II, IIA, III, or IV are described below.

After ~20 h., the reaction flask was allowed to warm to room temperature, and quenched with 70 mL methanol: dichloromethane (1:1 ratio, 0.016M). The reaction flask was placed back in the 20°C environment for 15 min., and then brought to alkaline conditions with 27% NH<sub>4</sub>OH. The neutralized crude was evaporated *in vacuo*, and the product was isolated via column chromatography on silica gel using 10% methanol in chloroform as the running solvent. 269.5 mg (73%) of the title nucleoside was isolated.

Biological ExamplesExample 1. Anti-Hepatitis C Activity

15           Compounds can exhibit anti-hepatitis C activity by inhibiting HCV polymerase, by inhibiting other enzymes needed in the replication cycle, or by other pathways. A number of assays have been published to assess these activities. A  
20 general method that assesses the gross increase of HCV virus in culture is disclosed in U.S. Patent No. 5,738,985 to Miles *et al.* *In vitro* assays have been reported in Ferrari *et al. Jnl. of Vir.*, 73:1649-1654, 1999; Ishii *et al., Hepatology*, 29:1227-1235, 1999; Lohmann *et al., Jnl of Bio. Chem.*, 274:10807-10815, 1999; and Yamashita *et al., Jnl. of Bio. Chem.*, 273:15479-15486, 1998.

25           WO 97/12033, filed on September 27, 1996, by Emory University, listing C. Hagedorn and A. Reinoldus as inventors, which claims priority to U.S.S.N. 60/004,383, filed on September 1995, describes an HCV polymerase assay that can be used to evaluate the activity of the of the compounds described herein. Another  
30 HCV polymerase assay has been reported by Bartholomeusz, *et. al.*, Hepatitis C Virus (HCV) RNA polymerase assay using cloned HCV non-structural proteins; Antiviral Therapy 1996:1(Supp 4) 18-24.

Screens that measure reductions in kinase activity from HCV drugs are disclosed in U.S. Patent No. 6,030,785, to Katze *et al.*, U.S. Patent No. Delvecchio *et al.*, and U.S. Patent No. 5,759,795 to Jubin *et al.* Screens that measure the protease inhibiting activity of proposed HCV drugs are disclosed in U.S. Patent No. 5,861,267 to Su *et al.*, U.S. Patent No. 5,739,002 to De Francesco *et al.*, and U.S. Patent No. 5,597,691 to Houghton *et al.*

#### Example 2. Replicon Assay

A cell line, ET (Huh-lucubineo-ET) is used for screening of compounds of the present invention for HCV RNA dependent RNA polymerase. The ET cell line is stably transfected with RNA transcripts harboring a I<sub>389</sub>luc-ubi-neo/NS3-3'/ET; replicon with firefly luciferase-ubiquitin-neomycin phosphotransferase fusion protein and EMCV-IRES driven NS3-5B polyprotein containing the cell culture adaptive mutations (E1202G; T1280I; K1846T) (Krieger *et al.*, 2001 and unpublished). The ET cells are grown in DMEM, supplemented with 10% fetal calf serum, 2 mM Glutamine, Penicillin (100 IU/mL)/Streptomycin (100 ug/mL), 1x nonessential amino acids, and 250 ug/mL G418 ("Geneticin"). They are all available through Life Technologies (Bethesda, MD). The cells are plated at 0.5-1.0 x10<sup>4</sup> cells/well in the 96 well plates and incubated for 24 hrs before adding nucleoside analogs. Then the compounds each at 5 and 50 uM will be added to the cells. Luciferase activity will be measured 48-72 hours later by adding a lysis buffer and the substrate (Catalog number Glo-lysis buffer E2661 and Bright-Glo leuciferase system E2620 Promega, Madison, WI). Cells should not be too confluent during the assay. Percent inhibition of replication will be plotted relative to no compound control. Under the same condition, cytotoxicity of the compounds will be determined using cell proliferation reagent, WST-1 (Roche, Germany). The compounds showing antiviral activities, but no significant cytotoxicities will be chosen to determine IC<sub>50</sub> and TC<sub>50</sub>.

#### Example 3. Cloning and expression of recombinant HCV-NS5b

The coding sequence of NS5b protein is cloned by PCR from pFKI<sub>389</sub>luc/NS3-3'/ET as described by Lohmann, V., *et al.* (1999) *Science* 285, 110-113 using the following primers:

aggacatggatccgcggggtcgggcacgagacag (SEQ. ID. NO. 1)

aaggctggcatgcactcaatgtcctacacatggac (SEQ. ID. NO. 2)

The cloned fragment is missing the C terminus 21 amino acid residues. The cloned fragment is inserted into an IPTG-inducible expression plasmid that provides  
5 an epitope tag (His)<sub>6</sub> at the carboxy terminus of the protein.

The recombinant enzyme is expressed in XL-1 cells and after induction of expression, the protein is purified using affinity chromatography on a nickel-NTA column. Storage condition is 10 mM Tris-HCl pH 7.5, 50 mM NaCl, 0.1 mM EDTA,  
10 1 mM DTT, 20% glycerol at -20 °C.

#### Example 4. HCV-NS5b Enzyme Assay

The polymerase activity is assayed by measuring incorporation of  
15 radiolabeled UTP into a RNA product using a poly-A template (1000-10000 nucleotides) and oligo-U<sub>12</sub> primer. Alternatively, a portion of the HCV genome is used as template and radiolabeled GTP is used. Typically, the assay mixture (50 µl) contains 10 mM Tris-HCl (pH7.5), 5 mM MgCl<sub>2</sub>, 0.2 mM EDTA, 10 mM KCl, 1 unit/µl RNasin, 1 mM DTT, 10 µM each of NTP, alpha-[<sup>32</sup>P]-GTP, 10 ng/µl polyA  
20 template and 1 ng/µl oligoU primer. Test compounds are dissolved in water containing 0 to 1% DMSO. Typically, compounds are tested at concentrations between 1 nM and 100 µM. Reactions are started with addition of enzyme and allowed to continue at room temperature or 30 °C for 1 to 2 hours. Reactions are quenched with 20 µl 10 mM EDTA and reaction mixtures (50 µl) spotted on DE81  
25 filter disc to capture the radiolabelled RNA products. After washing with 0.5 mM Na<sub>2</sub>HPO<sub>4</sub> (3 times), water (1 time) and ethanol (1 time) to remove unincorporated NTP, the discs are dried and the incorporation of radioactivity is determined by scintillation counting.
